

Important Information

The two most important things that can damage your skull if you don't pay attention to are:

1. **NEVER turn on the power supply before making all the connections to the terminals and making sure they are secure.** These connections are the 3 wires from your Grounded AC plug (Black, White, and Green) and the two power wires that go to the skull, Red (+) and Black (-)
2. **Be absolutely sure that the red wire that goes to the skull is connected to the positive DC output from the power supply, and the Black wire is connected to the negative DC output. On the Power supply, those are marked V+ and V-. If the polarity is connected backwards, you could fry the controller card and possibly all the servos as well.**

There is a lot of other important and useful information available on the website at the following links, that you should download and look over:

First, our set of documents:
